

**In the Abstract**

Please amend the Abstract as follows:

~~A~~ ~~What is disclosed is a~~ method for creating reusable composite components from interpreted pages of rendered document during dynamic document construction. ~~The method~~ involves first obtaining a list of document components from the page and identifying any non-cached components. The individual reusable document components (RDCs) are cached having been rendered to their respective bounding box dimensions. These RDCs are then permuted into combinations of RDCs and each composite RDC is cached rendered relative to each other in a bounding box of sufficient size to adequately contain the combination. Then, combining RDCs to form composite reusable underlays RULs and caching the composite RULs rendered to full-page size. Any portion of each RDC of each composite RUL falling outside the boundary of RULs full-page size is clipped. ~~If Also disclosed is a method for rendering renders~~ pages having a combination of reusable components and non-cached components, ~~has~~ the first step assesses ~~of assessing~~ the page for the possibility of having an underlay-overlay pair. Then a cache of RULs is searched for underlays having the needed RDCs. If the correct RUL is not found in cache then generating a RUL from the page's RDCs and caching the new RUL rendered to full-page size. A full-page size overlay is rendered having the non-cached components. Lastly, given the overlay and given the correct underlay is found in cache then retrieving the underlay and rendering the page therefrom.
